

GIVE FEEDBACK

CONTINUE >

This section is about **non-concurrent force** systems. A system of forces is called non-concurrent if the forces do not meet at a common point (a point of concurrency).

When forces are non-concurrent, it means that there is always a possibility that they may have a turning effect with respect to the structure or mechanical component. The **moment of a force** is introduced; it is a measure of a force's turning effect about the reference points.

In this section the concept of **general equilibrium** is introduced, along with the concept of **moments of a couple** and the analysis of an **equivalent force-couple system**.

In engineering, non-concurrent forces and moments are essential in designing the stability of structures and machines. Moments analyses are especially important in structures and beams bearing loads.

Characteristics of a system of non-concurrent forces

A system of forces is called **non-concurrent** if it does not have a single point of concurrency, i.e. the lines of action of the forces do not all meet at a common point.

When forces are non-concurrent, there is always a possibility that they may have a turning effect with respect to the structure or mechanical component to which they are applied. The concept of **moment of a force** is introduced; it is a measure of a force's turning effect about some reference point.

Equilibrium of non-concurrent forces requires that, in addition to the force balance, the moments of all forces must also be in balance.

Every time we drive a car, tighten up a nut, ride a bicycle or open a door, we make use of the turning effect of a force or forces, applied at some distance from the axis or fulcrum about which turning takes place.

The lever is only one example of the application of the **principle of moments**.

Levers enable us to multiply the force available in our own hands to move very large loads. Today the lever, in various forms and combinations, is the most common machine element.

GIVE FEEDBACK

Equations used to express the conditions of moment of a force

The **moment of a force** about a point is defined as the product of the force and the perpendicular distance of its line of action from the point.

$$M = F d$$

M = moment of a force about the point

F = force applied

d = the perpendicular distance of its line of action from the point

The perpendicular distance d is often referred to as the **moment arm** or **lever arm**.

The moment is a measure of the turning effect of the force acting on a body, relative to a specified point. As a product of force and distance, the moment of a force is measured in units derived from those of force and length.

Example

If a force of 65 N is applied to the lever shown in the figure below, and the length of the moment arm is 0.75 m, determine the moment of the force about the pivot point.

[GIVE FEEDBACK](#)[CONTINUE >](#)

Solution

Moment is the product of the force and the perpendicular distance called the moment arm:

$$\begin{aligned}M &= F d \\&= 65 \text{ N} \times 0.75 \text{ m} \\&= 48.75 \text{ N} \cdot \text{m clockwise}\end{aligned}$$

Note that the answer also indicates the directional sense of the moment, clockwise in this case. In this example, the actual length of the lever is in fact the moment arm at right angles to the force.

< BACK

GIVE FEEDBACK

OK

Example

In many problems, care must be exercised in using correct perpendicular distance with each force, as illustrated by the following example.

Determine the magnitude and sense of the moments of forces F_1 , F_2 and F_3 about point A in the following figure. In this example, drawing individual diagrams for each force will be very helpful to understand which distance is in fact the moment for each of the forces in question.

[GIVE FEEDBACK](#)[CONTINUE >](#)

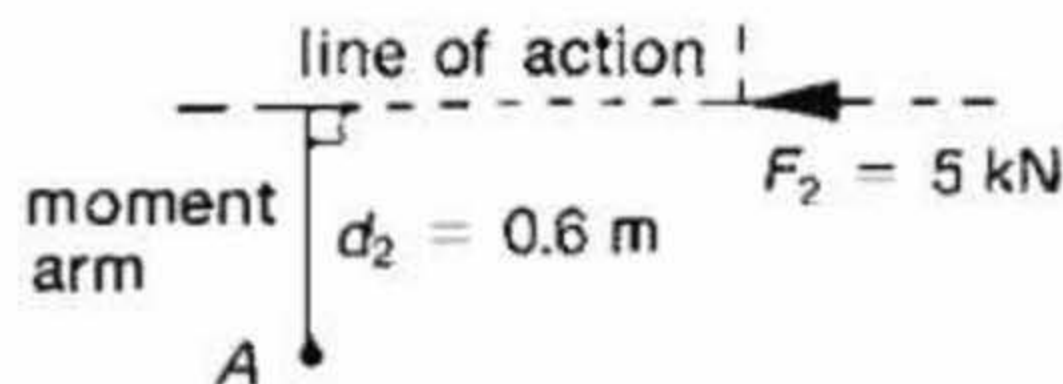

SolutionMoment of force F_1 :

$$\begin{aligned}M_1 &= F_1 d_1 \\&= 10 \text{ kN} \times 1 \text{ m} \\&= 10 \text{ kN m clockwise}\end{aligned}$$

Moment of force F_2 :

$$\begin{aligned}M_2 &= F_2 d_2 \\&= 5 \text{ kN} \times 0.6 \text{ m} \\&= 3 \text{ kNm anticlockwise}\end{aligned}$$

Moment of force F_3 :

$$\begin{aligned}M_3 &= F_3 d_3 \\&= 2 \text{ kN} \times 0 \\&= 0\end{aligned}$$

Note that force F_3 does not have a moment about point A due to the fact that its line of action passes through the point, i.e. its perpendicular distance from A is equal to zero.

$$\begin{aligned}M_2 &= F_2 d_2 \\&= 5 \text{ kN} \times 0.6 \text{ m} \\&= 3 \text{ kN m anticlockwise}\end{aligned}$$

SHOW ANSWER

Determine the moment of a force by calculating the correct moment arm (perpendicular distance)—Example 1/3

Example

If a force is inclined to the convenient principal directions, such as the horizontal and vertical directions, the correct perpendicular distance can be determined graphically in the following example.

Determine the moment of force $F = 50\text{ N}$ about point A if the distance AB is 800 mm .

GIVE FEEDBACK

CONTINUE >

Determine the moment of a force by calculating the correct moment arm (perpendicular distance)—Example 2/3

Solution

In this case the given distance AB is not the moment arm because AB is not perpendicular to the line of action of the force. To solve the problem we need distance AC . This can be found graphically or mathematically.

Graphically it can be done by drawing the diagram to scale and measuring the required distance AC . Mathematically it can be done by using trigonometry. Usually the mathematical method will generate a more reliable answer.

[< BACK](#)

[GIVE FEEDBACK](#)

[CONTINUE >](#)

Determine the moment of a force by calculating the correct moment arm (perpendicular distance)—Example 3/3

From the right-angled triangle ABC :

$$\begin{aligned}\text{Moment arm } d &= AB \sin 45^\circ \\ &= 0.8 \times 0.707 \\ &= 0.566 \text{ m}\end{aligned}$$

The moment of force is therefore:

$$\begin{aligned}M &= F d \\ &= 50 \text{ N} \times 0.566 \text{ m} \\ &= 28.3 \text{ N} \cdot \text{m clockwise}\end{aligned}$$

Turning effecting or resulting moment

If more than one force is acting on a body, there is a corresponding number of moments of force, each tending to produce a turning effect about the point.

The total turning effect, or resultant moment, is the algebraic sum of the moments of all the forces acting on the body.

This figure is showing that there are three forces acting around the point A.

Hence the total turning effect is the algebraic sum of the moments of all three forces acting around point A.

The algebraic sign convention of clockwise and anticlockwise moments

The total turning effect, or resultant moment, is the algebraic sum of the moments of all the forces acting on the body.

Algebraic sum means that the different directional sense of the various moments must be taken into account when the moments are being added.

For mathematical calculations, a sign convention usually used is that clockwise moments are taken to be positive and anticlockwise moments to be negative.

In this example, the three moments about point A can be calculated individually.

$$\begin{aligned}M_1 &= F_1 d_1 \\&= 10 \text{ kN} \times 1 \text{ m} \\&= 10 \text{ kN} \cdot \text{m} \text{ clockwise}\end{aligned}\quad \begin{aligned}M_2 &= F_2 d_2 \\&= 5 \text{ kN} \times 0.6 \text{ m} \\&= 3 \text{ kN} \cdot \text{m} \text{ anticlockwise}\end{aligned}\quad \begin{aligned}M_3 &= F_3 d_3 \\&= 2 \text{ kN} \times 0 \\&= 0\end{aligned}$$

Using the sign convention, the moments about point A can be shown as:

$$\begin{aligned}M_1 &= 10 \text{ kN} \cdot \text{m} \text{ clockwise} & M_2 &= 3 \text{ kN} \cdot \text{m} \text{ anticlockwise} \\&= + 10 \text{ kN} \cdot \text{m} & &= - 3 \text{ kN} \cdot \text{m}\end{aligned}$$

$$M_3 = 0$$

The conditions of rotational equilibrium for a system of forces

When a structure or a machine component is in **equilibrium**, the moments, as well as forces, must be in a state of balance, otherwise the unbalanced resultant moment would cause rotation of the body.

Thus for a body to be in **rotational equilibrium**, the resultant moment about any point must be equal to zero, i.e. there must be no resultant turning effect.

GIVE FEEDBACK

OK

Type your answer in the box.

For a body to be in rotational equilibrium, the resultant moment about any point must be equal to

The equation of rotational equilibrium for a system of forces

For a body to be in rotational equilibrium, the resultant moment about any point must be equal to zero.

Mathematically this can be stated as:

$$\Sigma M = 0$$

Alternatively this principle can be expressed in terms of equivalence of the sum of the clockwise moments about any point and the sum of anticlockwise moments about the same point. That is, for equilibrium:

Sum of clockwise moments = sum of anticlockwise moments

The simplest case of this relation is the equivalence of moments of two forces in static equilibrium about a pivot point.

GIVE FEEDBACK

OK

Which of the following equations correctly describe rotational equilibrium?

Check **all** that apply.

☐

$$\Sigma M = 0$$

☐

Sum of clockwise moments = sum of anticlockwise moments

☐

$$\Sigma F = 0$$

☐

$$M_1 + M_2 = 0$$

Example

The wheelbarrow shown below carries a load of 58 kg. Calculate the effort required to hold the handles in a stationary position.

GIVE FEEDBACK

CONTINUE >

Solution

First calculate the weight of the load:

$$\begin{aligned}F_w &= m g \\&= 58 \text{ kg} \times 9.81 \text{ N/kg} \\&= 569 \text{ N}\end{aligned}$$

Now equate the moments of the two forces about the pivot point, which is the axis of the wheel, and solve for the unknown force:

$$569 \times 0.52 = F_E \times 1.12$$

$$\therefore F_E = 264 \text{ N}$$

The total effort required is 264 N or 132 N per handle.

Determine the force F required to start to tip the cabinet shown below if the mass of the cabinet is 50 kg.

SMALL

Prove a given system of forces is in rotational equilibrium

1/2

To prove that a given system of forces is in rotational equilibrium, we must demonstrate that the algebraic sum of all moments about any point is zero.

A bridge structure is subjected to forces as shown below. Prove that the structure is in rotational equilibrium.

GIVE FEEDBACK

CONTINUE >

We must demonstrate that the algebraic sum of all moments about every point is zero.
Take the algebraic sum of all moments about the left-hand support A :

$$\Sigma M_A = 50 \times 20 + 10 \times 30 - 7.5 \times 8 - 31 \times 40$$

$$\Sigma M_A = 0$$

Therefore the moments are balanced about point A .

Take the algebraic sum of all moments about the right-hand support B :

$$\Sigma M_B = 29 \times 40 - 50 \times 20 - 10 \times 10 - 7.5 \times 8$$

$$\therefore \Sigma M_B = 0$$

Therefore the moments are balanced about point B .

Type your answer in the box.

The three conditions of equilibrium for a system of non-concurrent forces

It has already been established that for a system of forces to be in equilibrium, the resultant force, i.e. the result of vectorial summation of all forces, must be equal to zero. That is, there must be no resultant push or pull.

This statement is often interpreted mathematically in terms of the perpendicular, usually horizontal and vertical, components of the resultant force and can be stated simply as:

$$\Sigma F_x = 0 \text{ and } \Sigma F_y = 0$$

Only when both of these conditions are satisfied is the force equilibrium established.

These two conditions were found sufficient for the study of equilibrium of concurrent force systems. However, under certain conditions rotation may occur.

An additional condition for equilibrium of a system of non-concurrent forces must, therefore, ensure the absence of a turning moment, stated as:

$$\Sigma M = 0$$

GIVE FEEDBACK

OK

Select the correct conditions required for equilibrium of a system of non-concurrent forces.

Check **all** that apply.

- ☐ The resultant sum of all horizontal component forces must equal zero
- ☐ The resultant sum of all vertical component forces must equal zero
- ☐ There must be no resultant turning moment about any points
- ☐ The body must remain stationary

Prove a given structure is in static equilibrium

The structure is subjected to forces as shown below.

Using the three equations of statics, prove that the structure is in equilibrium.

Problem	Equations	Step 1	Step 2	Step 3	Conclusion
---------	-----------	--------	--------	--------	------------

Prove a given structure is in static equilibrium

The three equations of static areas follow.

The sum of x components of all forces must equal zero:

$$\Sigma F_x = 0$$

The sum of y components of all forces must equal zero:

$$\Sigma F_y = 0$$

The sum of moments of all forces about any point must equal zero:

$$\Sigma M = 0$$

Problem	Equations	Step 1	Step 2	Step 3	Conclusion
---------	-----------	--------	--------	--------	------------

Prove a given structure is in static equilibrium

Note the algebraic sign convention for left direction force is negative and right direction force is positive,

From the figure we can identify two horizontal forces.

Hence the sum of horizontal forces:

$$\Sigma F_x = 40 \text{ kN} - 40 \text{ kN} = 0$$

Problem	Equations	Step 1	Step 2	Step 3	Conclusion
---------	-----------	--------	--------	--------	------------

Prove a given structure is in static equilibrium

Note the algebraic sign convention for down-direction force is negative and up-direction force is positive.

From the figure we can identify four vertical forces.

Hence the sum of vertical forces:

$$\Sigma F_y = 22 \text{ kN} + 10 \text{ kN} - 20 \text{ kN} - 12 \text{ kN} = 0$$

Problem

Equations

Step 1

Step 2

Step 3

Conclusion

GIVE FEEDBACK

OK

Prove a given structure is in static equilibrium

Try calculating moments about an alternative point, e.g. the right-hand support, to be satisfied that the sum of the moments is equal to zero irrespective of the position of the reference point.

$$\Sigma F_y = 22 \text{ kN} + 10 \text{ kN} - 20 \text{ kN} - 12 \text{ kN} = 0$$

Sum of moments about left-hand support:

$$\Sigma M = 20 \times 4 - 10 \times 8 + 12 \times 6 - 40 \times 1.8 = 0$$

Note the algebraic sign convention for anticlockwise direction force is negative and clockwise direction force is positive.

All three equations are satisfied. The conclusion is that the structure is in static equilibrium.

Problem	Equations	Step 1	Step 2	Step 3	Conclusion
---------	-----------	--------	--------	--------	------------

Prove a given structure is in static equilibrium

Proving equilibrium of a static structure, such as a truss or a bridge span, when all forces (i.e. all loads and all reactions) acting on it are known and taken into account does not in itself seem to be much more than a mathematical exercise of confirming by calculation the obvious fact that any static structure must always be in equilibrium.

It is quite a different matter when some of the forces, usually support reactions, are not given.

In this case the three equations of statics become a powerful tool which enables us to calculate up to three unknown reaction forces for any structure which is presumed to be in equilibrium. This will be made use of for the analysis of beams, frames and trusses.

Resultant of non-concurrent force system

In studying concurrent forces and static equilibrium, we learned that the resultant force has that single force which has exactly the same effect as a given system of forces.

We also learned how to determine its magnitude and direction by the force polygon method or by mathematical addition of forces.

This is applicable to the case of non-concurrent forces acting on a rigid body, except that each force in such a system will also tend to rotate the body upon which it acts about some axis.

In order to determine the resultant of a non-concurrent force system, it is therefore necessary to consider the rotational effect of the force system in addition to the linear push–pull action of the forces.

GIVE FEEDBACK

OK

What is the main difference between determining the resultant of a concurrent force system and a non-concurrent force system?

Click the correct answer.

It is necessary to consider the rotational effect of the force system in a non-concurrent force system (in addition to the linear push-pull forces).

There is no difference.

When the resultant of a non-concurrent force system is not zero, it is can still be in equilibrium.

Mathematical addition of forces does not apply to a non-concurrent force system.

Do you know the answer?

I KNOW IT

THINK SO

UNSURE

NO IDEA

Steps required to solve for the resultant of non-concurrent forces

When solving for the resultant of a non-concurrent force system, the problem usually consists of two steps:

1. Finding the magnitude and direction of the resultant force by mathematical or graphical addition of all forces

2. Finding the location of the resultant relative to an arbitrary reference point, usually by applying the principle of moments

1

Finding the magnitude and direction of the resultant force by mathematical or graphical addition of all forces

Step
2

Finding the location of the resultant relative to an arbitrary reference point, usually by applying the principle of moments

Do you know the answer?

I KNOW IT

THINK SO

UNSURE

NO IDEA

Example

A concrete foundation for a brick wall must support two vertical loads and a horizontal load due to soil pressure on one side, as shown below. Its own weight is also shown. Determine the resultant and check if it passes through the base of the foundation, as required for stability.

Solution

Sum of vertical forces:

$$\begin{aligned}\Sigma F_V &= 106 + 72 + 72 \\ &= 250 \text{ kN down}\end{aligned}$$

Sum of horizontal forces:

$$\Sigma F_H = 64 \text{ kN to the right}$$

Addition of forces states that by arranging given forces in a tip-to-tail fashion, the resultant of the forces is found by connecting the tail of the first force and the tip of the last force.

Determine the magnitude, direction and location of the resultant of the system of forces—Example

Sum of vertical forces:

$$\begin{aligned}\Sigma F_V &= 106 + 72 + 72 \\ &= 250 \text{ kN down}\end{aligned}$$

Sum of horizontal forces:

$$\Sigma F_H = 64 \text{ kN to the right}$$

The resultant of the forces can now be solved by mathematical or graphical methods.

Using Pythagoras's theorem the resultant is:

$$\begin{aligned}F &= \sqrt{250^2 + 64^2} \\ &= 258.1 \text{ kN}\end{aligned}$$

< BACK

GIVE FEEDBACK

CONTINUE >

The angle to the horizontal:

$$\theta = \tan^{-1} \left(\frac{250}{64} \right)$$

$$= 75.6^\circ$$

To locate the resultant, take moments about a convenient point, such as midpoint of the base:

$$\begin{aligned} \Sigma M &= 64 \times 0.4 - 72 \times 0.12 + 72 \times 0.12 \\ &= 25.6 \text{ kN} \cdot \text{m} \end{aligned}$$

Parts of this solution can also be done graphically. For example, the magnitude and direction of the resultant can conveniently be found by constructing the polygon of forces. However, the principle of moments, for determining the distance d is best dealt with mathematically.

The alternative graphical method, known as the funicular (from funis meaning rope) polygon, involves a special construction procedure which locates a point on the line of action of the resultant force, thus locating the force itself. It is not discussed here.

Determine the magnitude, direction and location of the resultant of the system of forces—Example

Distance of the resultant from the midpoint:

$$\begin{aligned} d &= \frac{\Sigma M}{F} \\ &= \frac{25.6 \text{ kN} \cdot \text{m}}{258.1 \text{ kN}} \\ &= 0.0992 \text{ m} \\ &= 99.2 \text{ mm} \end{aligned}$$

The point at which the resultant intersects with the base can be calculated from:

$$\begin{aligned} OB &= \frac{d}{\sin 75.6^\circ} \\ &= \frac{992}{\sin 75.6^\circ} \\ &= 102.4 \text{ mm} \end{aligned}$$

< BACK

GIVE FEEDBACK

OK

When solving for the resultant of a non-concurrent force system, the problem usually consists of two steps:

1. Finding the magnitude and direction of the resultant force by mathematical or graphical addition of all forces
2. Finding the location of the resultant relative to an arbitrary reference point, usually by applying the principle of moments

Here we can use the two-steps method to determine the magnitude, direction and location of the resultant of the system of forces.

[GIVE FEEDBACK](#)[CONTINUE >](#)

Determine the magnitude, direction and location of the resultant of the system of forces

2/4

The magnitude of the resultant force:

$$\begin{aligned} F &= \Sigma F \\ &= -10 + 15 - 19 - 8 \\ &= -22 \text{ kN} \end{aligned}$$

That is, 22 kN down.

< BACK

GIVE FEEDBACK

CONTINUE >

The location is found by taking moments about an arbitrary point, such as point A :

$$\begin{aligned}\Sigma M &= 10 \times 0 - 15 \times 1 + 19 \times 2 + 8 \times 4 \\ &= 55 \text{ kN} \cdot \text{m}\end{aligned}$$

This sum must be equal to the moment of the resultant about the same point:

$$\begin{aligned}F \times d &= 55 \text{ kN} \cdot \text{m} \\ 22 \text{ kN} \times d &= 55 \text{ kN} \cdot \text{m} \\ \therefore d &= \frac{55 \text{ kN} \cdot \text{m}}{22 \text{ kN}} \\ &= 2.5 \text{ m}\end{aligned}$$

Determine the magnitude, direction and location of the resultant of the system of forces

4/4

It is therefore possible to replace the given system of forces by a single downward force of 22 kN, located at 2.5 m from point A , as shown.

Force couple

We can determine the turning effects of single forces.

A **couple** consists of two forces which have:

1. The same magnitude
2. Parallel lines of action
3. Opposite sense

Forces on a steering wheel illustrating a couple

A couple is a pair of actual forces applied to a structure or component at specified points. A couple always consists of equal and opposite forces acting along parallel lines.

When your hands are on two opposite points of the steering wheel of a car, one hand pushing up and the other pulling down with equal but opposite forces, the result is a couple.

The algebraic sum of the two forces is equal to zero, i.e. there is no net push or pull in any direction.

However, we can see from the steering wheel that there will be an overall turning effect.

GIVE FEEDBACK

OK

OK

Which of the following are examples of a couple?

Check **all** that apply.

- ☐ Moving the steering wheel with two hands
- ☐ Turning a key in a lock
- ☐ Moving a steering wheel with one hand

A couple consists of two forces which have:

Check **all** that apply.

- ☐ Same magnitude
- ☐ Parallel lines of action
- ☐ Different magnitude
- ☐ Opposite direction sense
- ☐ Same direction sense

Do you know the answer?

I KNOW IT

THINK SO

UNSURE

NO IDEA

Moment of a couple is a pure turning effect produced by the couple, expressed in newton metres. A couple has no resultant force in any direction; the pair of forces cancel each other out.

When your hands are on two opposite points of the steering wheel of a car, one hand pushing up and the other pulling down with equal but opposite forces, the result is a couple.

Even though there is no net push or pull in any direction, there is a turning effect on the wheel.

The turning effect can be calculated relative to any point. The obvious point of reference for calculating the moments is the centre point of the wheel, which is the axis of its rotation.

The total moment is:

$$M = F \times \frac{D}{2} + F \times \frac{D}{2}$$

$$= F \left(\frac{D}{2} + \frac{D}{2} \right)$$

$$= F \times D$$

F is the magnitude of each of the forces in the couple.

D is the distance between them, in this case the wheel diameter.

The sense of the total moment is clockwise for the forces shown.

The product of one of the forces and the distance between them is called the moment of the couple. One important characteristic of a couple is that its moment, $M = F \times D$, does not depend on the choice of the reference point. For example, the moment about point A is:

$$\begin{aligned}M_A &= F \times D + 0 \\&= F \times D\end{aligned}$$

This can be checked by repeating the same calculation about any other point on, or even outside, the wheel.

Select the statements that correctly describe the moment of couple.

Check **all** that apply.

- ☐ Moment of a couple is a pure turning effect produced by the couple
- ☐ A couple has no resultant force in any direction; the pair of forces cancel each other out
- ☐ A couple moment expressed in newtons
- ☐ The algebraic sum of forces is not zero, hence a pushing and turning effect

THINK SO

UNSURE

NO IDEA

Determine the moment of the couple acting on the steering wheel in the figure below if the wheel diameter is 350 mm and the forces applied as shown are each 5 N.

Also determine the forces required to produce the same moment if the hands are held on the spokes, halfway between the axis and the rim of the wheel.

Moment of the couple:

$$\begin{aligned}M &= F \times D \\&= 5 \text{ N} \times 0.35 \text{ m} \\&= 1.75 \text{ N} \cdot \text{m clockwise}\end{aligned}$$

To produce the same moment if the hands are held on the spokes, halfway between the axis and the rim of the wheel, where $D = \frac{0.35 \text{ m}}{2} = 0.175 \text{ m}$, the forces required can be calculated from $M = F \times D$:

$$\begin{aligned}1.75 \text{ N} \cdot \text{m} &= F \times 0.175 \text{ m} \\ \therefore F &= \frac{1.75 \text{ N} \cdot \text{m}}{0.175 \text{ m}} \\ &= 10 \text{ N each}\end{aligned}$$

SHOW ANSWER

Equivalent couple

Here are some important summary points.

1. A **couple** always consists of a pair of equal and opposite forces applied to a structure or component.
2. A **couple** has no resultant force in any direction; the pair of forces act along parallel lines and cancel each other out.
3. **Moment of a couple** is a pure turning effect produced by the couple, expressed in newton metres.

The magnitude of the moment of a couple is independent of the reference point about which it is calculated. Therefore, the simplest way to determine it is by multiplying one of the forces by the perpendicular distance between them.

The magnitude of the moment is also independent of the actual location of the couple on the structure or component to which it is applied. Therefore, a couple can be relocated to any other position without affecting the overall balance of moments.

An **equivalent couple** is any other couple with the same magnitude of turning moment and the same directional sense. A given couple can be replaced by an equivalent couple applied elsewhere on the body without changing its turning effect.

A given couple can be replaced by an equivalent couple applied elsewhere on the body without changing its effect.

Do you know the answer?

I KNOW IT

THINK SO

UNSURE

NO IDEA

Two forces systems are said to be **equivalent** if they result in the same resultant force (magnitude and direction) and produce the same resultant moment about any point.

When a force F is applied at a point on a rigid body, such as point A on the spanner shown in Figure (a), its effect can be viewed from some other significant point, such as the centreline of the bolt, point B .

In this case, the bolt (point B) experiences a downward push equal to the applied force F , as well as a clockwise turning moment M caused by force F about point B .

(a) Force applied to a spanner to turn a bolt

If we were to draw a separate diagram of the bolt itself, showing the effect of the applied force as viewed from B , the force F would be represented by the usual arrow symbol, and the turning moment indicated by the symbol \curvearrowright placed around point B , as shown in Figure (b).

(a) Force applied to a spanner to turn a bolt (b) The head of the bolt showing the turning moment

It is usually sufficient to leave the turning moment symbol as it is, without any further interpretation.

However, in reality, this pure turning moment is a result of a force couple acting on the head of the bolt, as shown in Figure (c).

In fact, if the distance between the flats of the hexagonal bolt head is known, it is possible to work out the magnitudes of the forces that constitute this couple.

- (a) Force applied to a spanner to turn a bolt (b) The head of the bolt showing the turning moment
(c) The force and couple acting on the head of the bolt

Diagrams (b) and (c) represent the force-and-moment system and force-and-couple system acting at point B , which is equivalent to the action of force F applied at point A .

Note that on both diagrams only the magnitude and clockwise directional sense of the turning moment are stated, without spelling out the individual force magnitudes in the pair.

There are situations, such as that illustrated by the following example, where it is necessary to know the individual forces in the couple and the perpendicular distance between them is well defined.

An equivalent force-couple system is a single force and a moment couple acting at a single point that is equivalent to the original set of forces and moments.

Example

A bolt is being tightened by a force of 60 N applied to a spanner at a distance of 300 mm, as shown below.

What is the force and turning moment acting on the bolt at point *B*?

Solution

If the distance between the flats of the hexagonal bolt head is known, it is possible to work out the magnitudes of the forces that constitute this couple.

- (a) Force applied to a spanner to turn a bolt (b) The head of the bolt showing the turning moment
(c) The force and couple acting on the head of the bolt

The force-moment system at *B* comprises a force of 60 N and a turning moment equal to:

$$\begin{aligned} M &= 60 \text{ N} \times 0.3 \text{ m} \\ &= 18 \text{ N} \cdot \text{m clockwise} \end{aligned}$$

Determine the equivalent force-moment system at point A (the built-in end of the cantilever beam) shown below.

Example

For the hook shown in Figure (a), replace the force of 200 N acting in plane A by an equivalent force-and-couple system at B .

Solution

The equivalent force-moment system at B consists of a force of 200 N and a clockwise turning moment equal to:

$$\begin{aligned} M &= 200 \text{ N} \times 0.075 \text{ m} \\ &= 15 \text{ N}\cdot\text{m} \end{aligned}$$

This is shown in Figure (b).

The effect of a given force acting on a body as an equivalent force-couple system acting elsewhere on the body—3/3
Example

In this case, where the moment is taken by the two screws, it is meaningful to interpret the moment as an equivalent couple with a distance of 50 mm between forces:

$$M = F d$$

$$15 \text{ N} \cdot \text{m} = F \times 0.05 \text{ m}$$

$$\begin{aligned}\therefore F &= \frac{15}{0.05} \\ &= 300 \text{ N}\end{aligned}$$

This is shown in Figure (c).
